Issues

Standard MCMC methods use a single Markov chain to explore the target distribution.

- Highly correlated variables → highly correlated output, slow mixing of the chain.
- Multi-modal target \rightarrow difficult to move between the modes.

A D M 4 目 M 4 日 M 4 1 H 4

• Choice of the proposal distribution is crucial for the performance of the algorithm.

Population MCMC methods

Parallel MCMC where the chains interact with one another.

The idea is to consider an augmented state space with stationary distribution,

$$\pi(\mathbf{x}) = \prod_{i=1}^n \pi_i(\mathbf{x}_i),$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ - 三 - のへぐ

where $\mathbf{x} = (\mathbf{x}_1, \dots, \mathbf{x}_n)$ and one or more of the $\pi_i(\cdot)$'s is exactly $\pi(\cdot)$.

Evolutionary Monte Carlo - Liang & Wong (2003)

Here, $\pi_i(\cdot) \propto {\pi(\cdot)}^{T_i}$ for i = 1, ..., n where $T_1 = 0, ..., T_n = 1$. The intermediate distributions $\pi_i(\cdot)$ are flattened versions of the target.

The algorithm works by

- 1. Updating in turn each \mathbf{x}_i from $\pi_i(\cdot)$.
- 2. Proposing to swap information from chain *i* to chain *i**, ie at time *t*

$$(\mathbf{x}_1^{(t)},\ldots,\mathbf{x}_i^{(t)},\ldots,\mathbf{x}_{i^*}^{(t)},\ldots,\mathbf{x}_n^{(t)}) \to (\mathbf{x}_1^{(t)},\ldots,\mathbf{x}_{i^*}^{(t)},\ldots,\mathbf{x}_i^{(t)},\ldots,\mathbf{x}_n^{(t)})$$

Snooker algorithm - Roberts & Gilks (1994)

Choose two points from current population.

Move one of the chosen points along the direction of the line formed by the two points.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

The simplex method - Nelder and Mead (1965)

Main idea is to move the vertex with the smallest target value from a low probability valley to a higher probability area.

- Simplex: a n + 1 polytope in n dimensional space, i.e a triangle in two dimensions, a tetrahedron in three dimensions etc.
- A local maximum is achieved by moving points of the simplex around the surface at each iteration in a deterministic way.

Reflection move of the simplex method.

◆□▶ ◆□▶ ◆三▶ ◆三▶ - 三 - のへぐ

The simplex sampler

Several MCMC chains that run in parallel and interact using ideas of the Nelder and Mead simplex method.

A D M 4 目 M 4 日 M 4 1 H 4

Three different type of moves are applied:

- Reflection
- Expansion and Contraction.
- Metropolis-Hastings update.

Reflection move

At time t

- 1. Choose $\mathbf{x}_i^{(t)}, i = 1, ..., n$ which tends to be the one with the smallest target probability compared to the rest of the population.
- 2. Estimate the centroid, $\mathbf{\bar{x}}^{(t)}$
- 3. Draw α from $p_{\alpha}(\cdot)$.

4. Estimate
$$\mathbf{y}_i = (1+lpha)\,ar{\mathbf{x}}^{(t)} - lpha \mathbf{x}^{(t)}_i$$

5. Accept the proposed point with probability

$$\alpha\left(\mathbf{x}_{i}^{(t)},\mathbf{y}_{i}\right) = \min\left\{1,\frac{\pi(\mathbf{y}_{i})}{\pi(\mathbf{x}_{i}^{(t)})}\frac{q(\mathbf{y}_{i},\mathbf{x}_{i}^{(t)})}{q(\mathbf{x}_{i}^{(t)},\mathbf{y}_{i})}\right\}$$

where $q(\mathbf{x}_i^{(t)}, \mathbf{y}_i)$ is the probability of choosing the current point times the probability of choosing α .

Reflection move

Expansion/Contraction move

- 1. Choose the expansion/contraction coefficient β from some distribution $p_{\beta}(\cdot)$.
- 2. Propose new vertex of the simplex

$$\mathbf{y}_i = \beta(\mathbf{x}_i^{(t)} - \bar{\mathbf{x}}^{(t)}) + \bar{\mathbf{x}}^{(t)}, \ i = 1, \dots, n$$

3. Accept proposed move with probability

$$\min\left(1,\frac{\pi(\mathbf{y})p_{\beta}(\beta^{*})}{\pi(\mathbf{x}^{(t)})p_{\beta}(\beta)}\right).$$

Example 1 - Mixture of two normals with unknown means

$$wN(\mu_1, \sigma^2) + (1 - w)N(\mu_2, \sigma^2)$$

where μ_1 , μ_2 are unknown and w, σ^2 are known.

Generate 1,000 points from 0.2N(0,1) + 0.8N(2,1).

Prior Distribution: N(1, 10).

Note: The total number of iterations for each algorithm was kept constant accounting for the differing number for iterations per sweep for each algorithms.

Conclusions

- High correlation \rightarrow Good mixing under the modes.
- Multi-modal target \rightarrow It gets trapped under a mode.

Nelder and Mead simplex method is a deterministic optimization algorithm...

Tempered simplex sampler

 $\pi(\cdot)$ is a *d* dimensional distribution of interest. $\mathbf{X} = (\mathbf{x}_1, \dots, \mathbf{x}_n)$: the current population. $\mathbf{x}_i = (\mathbf{x}_{i1}, \dots, \mathbf{x}_{im})$ with $\mathbf{x}_{ij} \in \mathbb{R}^d$ for $i = 1, \dots, n$ and $j = 1, \dots, m$. The temperature ladder is $T = (T_1, \dots, T_n)$ with $T_1 = 0 \le T_2 \le \dots \le T_n = 1$.

$$\pi(\mathbf{X}) = \prod_{i=1}^n \pi^{T_i}(\mathbf{x}_i)$$

and

$$\pi^{T_i}(\mathbf{x}_i) = \prod_{j=1}^m \pi^{T_i}(\mathbf{x}_{ij}).$$

Tempered simplex sampler - Step 1

• Update the simplex within each temperature, i.e

 $\mathbf{x}_i = (\mathbf{x}_{i1}, \dots, \mathbf{x}_{im})$ under temperature T_i .

- (i) Apply a reflection move.
- (ii) Apply an expansion/contraction move.
- (iii) Apply a Metropolis-Hastings move.

・ ロ ト ・ 雪 ト ・ 雪 ト ・ 日 ト

Tempered simplex sampler - Step 2

Current population $\mathbf{X} = (\mathbf{x}_1, \dots, \mathbf{x}_i, \dots, \mathbf{x}_l, \dots, \mathbf{x}_n)$ under $T = (T_1, \dots, T_n)$ with $T_1 = 0 \le T_2 \le \dots \le T_n = 1$.

 Exchange the population x_i under temperature T_i with another population x_i under temperature T_i.

> (i) Set $\mathbf{y}_i = \mathbf{x}_I$ under T_i and $\mathbf{y}_I = \mathbf{x}_i$ under T_I . (ii) Accept the proposed move with probability

$$\min\left\{1, \left(\frac{\pi(\mathbf{x}_i)}{\pi(\mathbf{x}_l)}\right)^{T_l - T_i}\right\}.$$

Then the new population is $(\mathbf{x}_1, \ldots, \mathbf{x}_l, \ldots, \mathbf{x}_i, \ldots, \mathbf{x}_n)$.

The tempered simplex sampler

The tempered simplex sampler borrows

- the good mixing of the simplex sampler in case of high correlated target distributions.
- the good mixing of the tempering methods that are able to traverse the entire sampling space without being trapped under a single maximum.

Example - Mixture of twenty normal distributions

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

Results - Mixture of twenty normal distributions

Modes	A	В	С	D
target	5%	15%	5%	10%
